

FIRST ASSIGNMENT

Task Manager App

In this assignment, you will create a Task Manager application that allows users to add, complete, and list tasks. This application will help users manage their daily tasks more efficiently. **It's important that you create a GitHub repository that is set to private.**

Start date: 2024.03.22

End date: 2024.04.19

You'll hand in the assignment using the link in this course (see hand in assignment step). Do not forget to invite both me and Kicki to your repository.

Main Components:

1. An object called **taskManager** that will contain all of your logic.
2. A function called **menu()** that displays different choices for the user and, based on the user's choice, shows the correct method/property from the **taskManager** object.
3. A function called **askUserName()** that should ask the user to enter their name before they can start using the Task Manager App. If the user enters a correct input display a welcome message containing the users name.

1 taskManager object

The **taskManager** object should have the following properties:

tasks: an array that holds all tasks. Each task is an object containing at least a description (string) and a completed (boolean) status. The array can be empty at the start.

addTask: a function that adds a new task to the tasks array. Each task should have a unique identifier (e.g., a numeric ID) for easy management.

FIRST ASSIGNMENT Task Manager App

completeTask: a function that marks a task as completed by changing its completed status.

listAllTasks: a function that lists all tasks, showing their ID, description, and completion status.

listCompletedTasks: a function that lists only the tasks that have been completed.

Ensure to handle potential errors, such as adding a task with an empty description or attempting to complete a task that does not exist.

2 menu() function

The **menu()** function should do the following:

- Displays a menu with different choices for the user: **add a task, complete a task, list all tasks**, and **list completed tasks**.
- Depending on what the user selects from the menu, call the correct method or property from the **taskManager** object. You can use a switch or if/else statement for your different menu choices. **Please motivate your choice in a comment.**

Before the user can start using the Task Manager App you should ask them to enter their name. You need to create a method called **askUserName()** which should do the following:

- Ask the user to enter their name

FIRST ASSIGNMENT Task Manager App

- If the user has entered a correct value, greet the user with a message containing their name and let the user start using the Task Manager App.
- If the user enters a incorrect value, like leave the field empty or adding an int, display an error message to the user and let the user try again.

You do not need to use any HTML or CSS in this assignment, only JavaScript. There are some starter code that you can clone. You'll find the link in the section for the first assignment.

In the starter code I show you how to use the `prompt()` and the `alert()` so you can get started with using an interface to display the menu without using HTML or CSS.

Good Luck!
